

Where to put arrays?

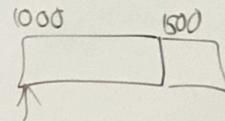

Array allocation strategies.

- Static allocation
(before program runs)

- + no run overhead
- + no crashes due storage exhaustion.
- + Compiler can optimize more.
 - hassle to change sizes—recompile
 - overallocation is common.
 - hard to have temp arrays

For next time

Dybvig SS 1 - 3.4
(Scheme)

Stack allocation (Size is statically known)

all memory needed

```
int f(int n) {  
    char buf[500];  
    char buf[1200];  
}
```

known at compilation
1780 bytes total.

subq \$1780,%rsp
(do work).

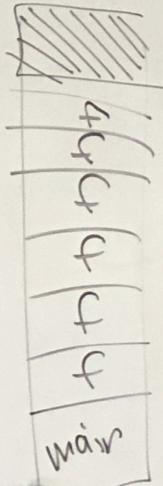

addq \$1780,%rsp

Array allocation is really fast if there's fixed stack allocation with static arrays
- used by C/C++

stack overflow problem

We see that with `char buf[5000]` we can jump straight over the guard page (which is 4 KiB min size)

other
stuff

guard page (4 kB min size)

int f(int n) {

char buff[5000];
return f(n);

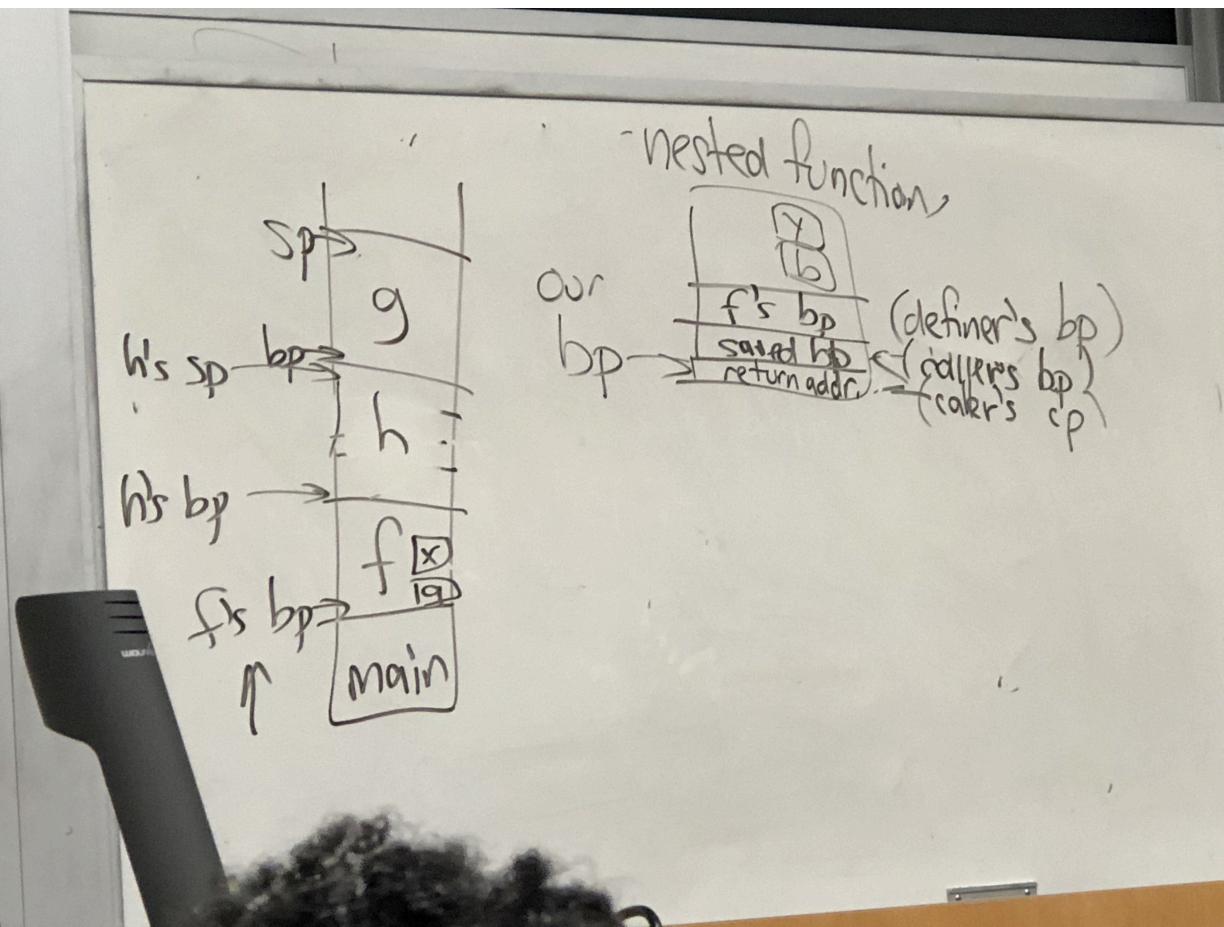

}
let x =

no x's here;

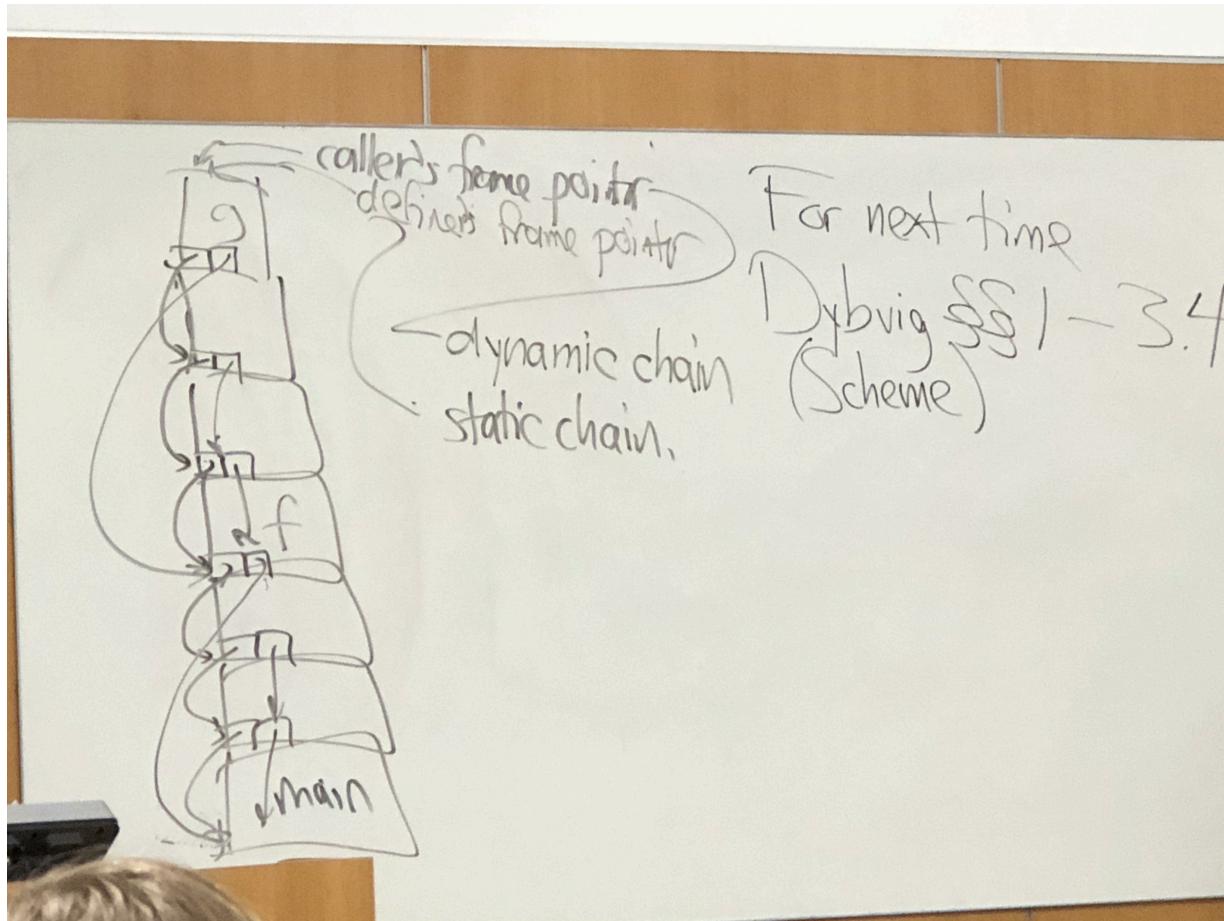

nesting functions

```
int main()
{
    int f (int x)
    {
        char a[100];
        int g(int y)
        {
            char b[200];
            return a[y] + b[x];
        }
        int h( ) hard
    }
}
```

Nested functions need function pointers.

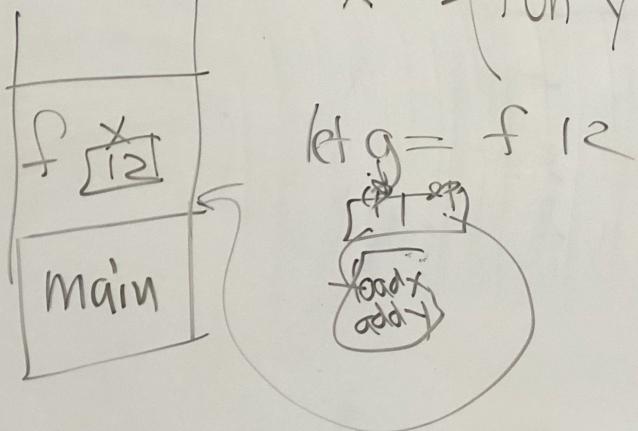

activation records = stack frames

In OCaml, there is no such thing as activation records on STACK

- doesn't use stack.
- Uses heap

nested functions + frames that survive function return.

let $f x y = x + y$
let $f = \text{fun } x \rightarrow (\text{fun } y \rightarrow x + y)$ (+)

let $g = f 12$
